

COMP5421 Computer Vision, Spring 2021

Homework Assignment 0

Scipy Practice¹

This homework will not be graded. It is meant to provide some Python/Scipy practice exercises to ensure that coding will not be an obstacle for you during this course. However, it IS REQUIRED that you submit an attempt. Please follow the submission instructions at the end of the assignment. This and future assignments will assume that you are using Python 3+ and the latest Scipy libraries (numpy, matplotlib, etc). The recommended approach is to use the Anaconda Python 3 distribution.

1 Color Channel alignment

You have been given the red, green, and blue channels of an image² that were taken separately using an old technique that captured each color on a separate piece of glass³. These files are named `red.npy`, `green.npy`, and `blue.npy` respectively (in the `data` folder). Because these images were taken separately, just combining them in a 3-channel matrix may not work. For instance, Figure 1 shows what happens if you simply combine the images without shifting any of the channels.

Your job is to take 3-channel RGB (red-green-blue) image and produce the correct color image (closest to the original scene) as output. Because in the future you may be hired to do this on hundreds of images, you cannot hand-align the image; you must write a function that finds the best possible displacement.

The easiest way to do this is to exhaustively search over a window of possible displacements for the different channels (you can assume the displacement will be between -30 and 30 pixels). Score the alignment from each possible displacement with some heuristic and choose the best alignment using these scores. You can use the following metrics:

1. Sum of Squared Differences (SSD)

This metric tries to compare the distance between two vectors, hence we can use this to compare image pixel intensity differences. For two vectors \mathbf{u} , \mathbf{v} of length N , this metric is defined as

$$SSD(u, v) = \sum_{i=1}^N (\mathbf{u}[i] - \mathbf{v}[i])^2$$

(essentially like the Euclidean distance metric).

2. Normalized Cross Correlation (NCC)⁴

This metric compares normalized unit vectors using a dot product, that is for vectors \mathbf{u} , \mathbf{v} ,

$$NCC(\mathbf{u}, \mathbf{v}) = \frac{\mathbf{u}}{\|\mathbf{u}\|} \cdot \frac{\mathbf{v}}{\|\mathbf{v}\|}$$

Implement an algorithm which finds the best alignment of the three channels to produce a good RGB image; it should look something like Figure 2. Try to avoid using for loops when computing

Figure 2: Aligned image

the metrics (SSD or NCC) for a specific offset. Some starter code is given in `script1.py` and `alignChannels.py`. Save your result as `rgb output.jpg` in the `results` folder.

2 Image warping

We will be writing code that performs affine warping on an image. Code has been provided to get you started. In the following sections you will be adding your own code.

2.1 Example code

The file `script2.py` contains example code which demonstrates basic image loading and displaying as well as the behavior of an image warping function. Try running `script2`. You should see something like Figure 3. This script calls the function `warp` in `warpA_check.py`, which is simply a wrapper for `scipy`'s own function `scipy.ndimage.affine_transform`.

Figure 3: See `script2.py`

2.2 Affine warp

You will write your own function in `warpA.py`, that should give the same output as the function in `warpA_check.py`. First we'll walk through what you need to know about affine transformations.

An affine transform relates two sets of points:

$$\mathbf{p}_{warped}^i = \underbrace{\begin{pmatrix} a & b \\ c & d \end{pmatrix}}_{\mathbf{L}} \mathbf{p}_{source}^i + \mathbf{t} \quad (1)$$

where \mathbf{p}_{source}^i and \mathbf{p}_{warped}^i denote the 2D coordinates (e.g., $\mathbf{p}_s^i = (\mathbf{x}_s^i, y_s^i)^T$) of the i -th point in the source space and destination (or warped) space respectively, \mathbf{L} is a 2×2 matrix representing the linear component, and \mathbf{t} is a 2×1 vector representing the translational component of the transform.

To more conveniently represent this transformation, we will use homogeneous coordinates, i.e., \mathbf{p}_s^i and \mathbf{p}_w^i will now denote the 2D homogeneous coordinates (e.g., $\mathbf{p}_s^i \equiv (\mathbf{x}_s^i, \mathbf{y}_s^i, 1)^T$), where “ \equiv ” denotes equivalence up to scale, and the transform becomes:

$$\mathbf{p}_d^i \equiv \underbrace{\begin{pmatrix} \mathbf{L} & \mathbf{t} \\ 0 & 0 \end{pmatrix} \mid 1}_{\mathbf{A}} \mathbf{p}_s^i \quad (2)$$

- Implement a function that warps image `im` using the affine transform `A`:

```
warp_im = warpA(im, A, output_shape)
```

Inputs: `im` is a grayscale `double` typed Numpy matrix of dimensions `height × width × 5`, `A` is

⁵Images in Numpy are indexed as `im(row, col, channel)` where `row` corresponds to the y coordinate (height), and `col` to the x coordinate (width).

a 3×3 non-singular matrix describing the transform ($\mathbf{p}_{warped}^i \equiv \mathbf{A}\mathbf{p}_{source}^i$), and `output_size=[out_height, out_width]`; of the warped output image.

Outputs: `warp_im` of size `out_size(1) × out_size(2)` is the warped output image.

The coordinates of the sampled output image points \mathbf{p}_{warped}^i should be the rectangular range $(0,0)$ to $(width - 1, height - 1)$ of integer values. The points \mathbf{p}_{source}^i must be chosen such that their image, $\mathbf{A}\mathbf{p}_{source}^i$, transforms to this rectangle.

Implementation-wise, this means that we will be looking up the value of each of the destination pixels by sampling the original image at the computed \mathbf{p}_{source}^i . (Note that if you do it the other way round, i.e., by transforming each pixel in the source image to the destination, you could get “holes” in the destination because the mapping need not be 1 to 1). In general, the transformed values p_{source} will not lie at integer locations and you will therefore need to choose a sampling scheme; the easiest is nearest-neighbor sampling (something like, `round(psourcei)`). You should be able to implement this without using `for` loops (one option is to use `numpy.meshgrid` and Numpy’s multidimensional indexing), although it might be easier to implement it using loops first. Save the resulting image in `results/transformed.jpg`.

You should check your implementation to make sure it produces the same output as the warp function provided in `warpA_check.py` (for grayscale or RGB images). Obviously the purpose of this exercise is practicing Python/Scipy by implementing your own function without using anything like `scipy.ndimage.affine_transform`.

3 Submission and Deliverables

Please submit a zip file to CASS for this homework of the form `<ust-login-id>.zip`. Running `script1.py` and `script2.py` from within the `code/` folder should produce the outputs `transformed.jpg`, and `rgb_output.jpg` in the `results/` folder. You should not include the `data/` folder in your submission. An example submission zip file should be:

`sigbovik.zip`:

- `code/`
 - `script1.py`
 - `script2.py`
 - `warpA.py`
 - `warpA_check.py`
 - any other files your code needs to run
- `results/`
 - `rgb_output.jpg` for Question 1
 - `transformed.jpg` for Question 2
